

## Three-Channel Flash LED Driver with Independent Current Control

### Features

- High efficiency synchronous boost converter with 2MHz/4MHz switching frequency option
- I<sup>2</sup>C interface programming and hardware STROBE/TORCH control
- Two current sources and one current sink
  - ▶ LED1: Up to 1.5A (7 bits)
  - ▶ LED2: Up to 0.75A (6 bits)
  - ▶ LED3: Up to 0.3A (6 bits)
  - ▶ Flash/Torch/IR modes
  - ▶ Independent LED on/off and current settings
  - ▶ Programmable ramp shape and time control
  - ▶ Three input low voltage protection modes
  - ▶ Flash time-out protection
  - ▶ LED cathode ground connection for improved thermal dissipation (LED1/LED2)
- LED open/short protection
- I<sup>2</sup>C fault read back (I<sup>2</sup>C address = 0x63)

### Applications

- Smartphones and Tablets Camera Flash
- Digital Cameras

### Brief Description

KTD2683B is the ideal power solution for high-power flash LEDs. It includes a highly integrated synchronous boost converter, two current sources and one current sink, providing a very small total solution in portable application. It has both I<sup>2</sup>C interface and hardware STROBE/TORCH pins for maximum control flexibility. The two integrated current sources and one current sink are independently controlled, their on/off conditions and current settings in Flash/Torch/IR modes can be programmed independently by the I<sup>2</sup>C interface. It also has three selectable input low voltage protection modes to prevent a system reset under low battery condition. Thermal regulation is also integrated to limit the IC temperature and continuously provide the maximum output current.

Various protection features are integrated into KTD2683B, including cycle-by-cycle input current limit protection, output over-voltage protection, LED fault (open or short) protection, flash timeout protection and thermal shutdown protection.

KTD2683B is available in a RoHS and Green 12-ball WLCSP package with 0.4mm pitch.

### Typical Application

## Pin Descriptions

Pin #	Name	Function
A1	GND	Ground pin
A2	VIN	Input supply pin for the device. Connect a 10µF ceramic capacitor to GND.
A3	SDA	Bi-direction data pin of the I <sup>2</sup> C interface.
B1	LX	Switching pin of the boost converter.
B2	STROBE	Active high FLASH/IR enable pin. There is an internal 300kΩ pull-down resistor at this pin to GND.
B3	SCL	Clock input pin of the I <sup>2</sup> C interface.
C1	VOUT	Output pin of the boost converter. Connect a 10µF ceramic capacitor to GND
C2	LED3	Regulated output current sink, up to 0.3A.
C3	TORCH	Active high TORCH enable pin. There is an internal 300kΩ pull-down resistor at this pin to GND.
D1	LED2	Regulated output current source #2, up to 0.75A.
D2	TX	Active high power amplifier synchronization input pin.
D3	LED1	Regulated output current source #1, up to 1.5A.

## Absolute Maximum Ratings<sup>1</sup>

(T<sub>A</sub> = 25°C unless otherwise noted)

Symbol	Description	Value	Units
VIN, VOUT	Input and output voltage pins	-0.3 to 6	V
LED1, LED2	Current source pins	-0.3 to VOUT+0.3	V
LED3	Current sink pin	-0.3 to VIN+0.3	V
SCL, SDA, STROBE, TX, TORCH	Control pins	-0.3 to VIN+0.3	V
LX	Switching pin	-0.3 to 6.5	V
T <sub>J</sub>	Operating Temperature Range	-40 to 150	°C
T <sub>S</sub>	Storage Temperature Range	-65 to 150	°C
T <sub>LEAD</sub>	Maximum Soldering Temperature (at leads, 10 sec)	300	°C
ESD	HBM electrical static discharge	2.0	kV

## Thermal Capabilities

Symbol	Description	Value	Units
θ <sub>JA</sub>	Thermal Resistance – Junction to Ambient <sup>2</sup>	90.2	°C/W
P <sub>D</sub>	Maximum Power Dissipation at T <sub>A</sub> ≤ 25°C	Internally Limited <sup>3</sup>	W
ΔP <sub>D</sub> /ΔT	Derating Factor Above T <sub>A</sub> = 25°C	-11.09	mW/°C

## Recommended Operating Range

Description	Value
VIN, VOUT, LED1, LED2, LED3	2.7V to 5.5V
LX	≤ 6V

## Ordering Information

Part Number	Marking	Operating Temperature	Package
KTD2683BEUD-TR	IBXXYYZZZZ <sup>4</sup>	-40°C to +85°C	WLCSP-12, 1.42mm x 1.66mm

- Stresses above those listed in Absolute Maximum Ratings may cause permanent damage to the device. Functional operation at conditions other than the operating conditions specified is not implied. Only one Absolute Maximum rating should be applied at any one time.
- Junction to Ambient thermal resistance is highly dependent on PCB layout. Values are based on thermal properties of the device when soldered to an EV board.
- Internal thermal regulation and shutdown circuitry protects the device from permanent damage. Thermal shutdown activated at typically T<sub>J</sub> = 150°C and re-engages at typically 130°C.
- XX = Date Code, YY = Assembly Code, ZZZZ = Serial Number.

**Electrical Characteristics<sup>5</sup>**

Unless otherwise noted, the *Min* and *Max* specs are applied over the full operation temperature range of -40°C to +85°C, while *Typ* values are specified at room temperature (25°C),  $V_{IN} = 3.6V$ ,  $V_{OUT} = 4V$ .

Symbol	Description	Conditions	Min	Typ	Max	Units
<b>VIN Supply</b>						
$V_{IN}$	Input operating range		2.7		5.5	V
$I_Q$	IC operating current	Not switching, pass mode		0.61		mA

## Functional Block Diagram

## Functional Description

KTD2683B is a high-power flash LED driver capable of delivering up to 1.5A for LED1, 0.75A for LED2 and 0.3A for LED3. It consists of a high switching frequency synchronous boost converter, two independently controlled current sources (LED1 and LED2 powered by the boost converter output) and one current sink (LED3 powered from VIN, pass mode only) in a small WLCSP package size. The inductor-based boost converter integrates two low  $R_{DS(on)}$  power MOSFETs, and operates at a switching frequency of 2.0MHz (default) or 4MHz to minimize the size of the external inductor and capacitors. Unlike a traditional DC-DC boost converter with a fixed output voltage, KTD2683B dynamically adjusts the output voltage depending on the flash LED1 and LED2 forward voltages and currents, it only boosts the output to a voltage sufficient to drive the LED1/LED2 at the programmed output current. The use of unique control scheme maintains accurate current regulation in the current sources while minimizing the output voltage, increasing the overall conversion efficiency. LED3 current comes from VIN directly without going through the boost converter loop, so it is ideal for low current Torch application, by saving the DC voltage drop across the inductor and boost converter PMOS.

The control interface is designed for maximum flexibility and compatibility with various types of system controls. KTD2683B is mainly programmed and controlled via an I<sup>2</sup>C-compatible interface, but also includes three logic inputs that can provide a hardware flash enable (STROBE) and a hardware torch enable (TORCH), as well as a flash interrupt (TX), which can be used to reduce the flash current during power amplifier pulse event to lower the battery load current. The I<sup>2</sup>C control features include the independent on/off and current control of the two current sources (LED1/LED2) in Flash/Torch/IR modes, their on/off ramp timing and current shape control, three input low voltage protection modes, flash safety time-out protection, boost converter current limit and switching frequency options, and various fault events read back. For the current sink LED3, the I<sup>2</sup>C interface can control its current value in Torch/IR modes. In addition, KTD2683B also has various protection features including LED open and short protections, thermal regulation to prevent IC temperature from going too high, and thermal shutdown protection.

**Standby Mode**

When both current sources (LED1, LED2) and the current sink (LED3) are disabled, the device stays in standby mode. But the I<sup>2</sup>C interface is enabled and the device can respond to I<sup>2</sup>C commands, the typical standby current from VIN pin is about 2.5μA. The power-up sequence is shown in Figure 2. Once VIN goes above around 2.0V for at least t<sub>wait</sub> = 150μs, the device can respond to I<sup>2</sup>C command.

**Figure 2. Power Up Sequence**

**Flash Mode (LED1/LED2)**

Only LED1 and LED2 can work in Flash mode, LED3 does not support Flash mode. In Flash mode, LED1 current can be programmed up to 1.5A (7 bits) and LED2 up to 0.75A (6 bits). The flash current values are controlled by I<sup>2</sup>C registers 0x03 and 0x04. LED2 current code in I<sup>2</sup>C register 0x04 has the option to be overridden by LED1 current code in I<sup>2</sup>C register 0x03. The flash on/off ramp time (ranging from 512μs to 64ms) is controlled by I<sup>2</sup>C register 0x07 bits[6:4], the shape of the ramp is always linear. The flash mode can be activated either by I<sup>2</sup>C register 0x01 bits[3:2] or by STROBE pin rising edge when STROBE pin is enabled, and it can be deactivated by I<sup>2</sup>C register 0x01 bits[3:2], or by STROBE pin, or by flash time-out event. After the flash time-out event, I<sup>2</sup>C register 0x01 bits[3:2] will be reset to standby mode.

If using STROBE pin to control the flash mode, there is an option to select when the flash mode is deactivated. If Strobe Type is selected as Level Triggered, flash mode is deactivated during STROBE pin falling edge or flash time-out event, as shown in Figure 3. If Strobe Type is selected as Edge Triggered, flash mode is only deactivated during flash time-out event, STROBE pin falling edge cannot deactivate it, as shown in .

**Figure 3. Flash Mode Current Controlled by STROBE (Level Triggered)**

**Figure 4. Flash Mode Current Controlled by STROBE (Edge Triggered)**

### Torch Mode

LED1/LED2/LED3 all can work in Torch mode. LED1 current can be programmed up to 187.5mA (7 bits), LED2 up to 187.5mA (6 bits) and LED3 up to 300mA (6 bits). LED1/LED2 torch current values are controlled by I<sup>2</sup>C registers 0x05 and 0x06. LED2 current code in I<sup>2</sup>C register 0x06 has the option to be overridden by LED1 current code in I<sup>2</sup>C register 0x05. LED1/LED2 torch on/off ramp time (ranging from 0 to 1024ms) is controlled by I<sup>2</sup>C register 0x08 bits[6:4], the shape of the ramp (exponential or linear) is controlled by I<sup>2</sup>C register 0x08 bit[7]. LED1/LED2 torch mode can be activated either by I<sup>2</sup>C register 0x01 bits[3:2] or by TORCH pin rising edge when TORCH pin is enabled, and it can be deactivated by I<sup>2</sup>C register 0x01 bits[3:2], or by TORCH pin falling edge. For LED3, its torch mode current is controlled by I<sup>2</sup>C register 0x0E bits[7:2], and its torch mode can be activated either by I<sup>2</sup>C register 0x0E bits[1:0] or by TORCH pin rising edge when TORCH pin is enabled, and it can be deactivated by I<sup>2</sup>C register 0x0E bits[1:0], or by TORCH pin falling edge. LED3 torch ramp is always linear with a fixed slope of 4.69mA/μs.

### IR Mode

LED1/LED2/LED3 can work in IR mode. LED1/LED2 IR mode current setting is similar to their Flash mode setting, which is controlled by I<sup>2</sup>C registers 0x03 and 0x04. LED2 current code in I<sup>2</sup>C register 0x04 has the option to be overridden by LED1 current code in I<sup>2</sup>C register 0x03. For LED1/LED2 IR mode, I<sup>2</sup>C register 0x01 bits[3:2] should be to '01' and STROBE pin should be enabled, then STROBE pin rising edge can activate LED1/LED2 IR mode, and STROBE pin falling edge or flash time-out event can deactivate LED1/LED2 IR mode. For LED3 IR mode, its current setting is similar to its Torch mode setting, which is controlled by I<sup>2</sup>C registers 0x0E bits[7:2]. I<sup>2</sup>C register 0x0E bits[1:0] should also be to '11' and STROBE pin should be enabled, then STROBE pin rising edge can activate LED3 IR mode, and STROBE pin falling edge can deactivate LED3 IR mode, but LED1/LED2 flash time-out event doesn't deactivate LED3 IR mode. In IR mode, the two current sources LED1/LED2 and the current sink LED3 are enabled to the full current setting with no delay or slow ramp during STROBE rising edge, and they are fully turned off immediately with no delay or slow ramp during STROBE falling edge. This allows IR current to follow the fast frequency IR transmission of the STROBE pin signal. For IR mode, STROBE pin only allows Level Triggered, and doesn't allow Edge Triggered, but LED1/LED2 are still protected by flash time-out if STROBE width is too long. In LED1/LED2 IR mode, since the STROBE width can be very short, the boost converter might not have enough time to boost the output high enough to regulate the current sources, it is recommended to set the boost converter to Pass mode and let the output voltage be equal to the input voltage.

Table 1 and Table 2 summarize the control of Standby/Flash/Torch/IR modes for LED1/LED2 and LED3.

**Table 1. LED1/LED2 Mode Control Table**

I <sup>2</sup> C register 0x01 bits[3:2]	STROBE Enable	TORCH Enable	STROBE Pin	TORCH Pin	FUNCTION
00	0	0	X	X	LED1/LED2 Off
00	0	1	X	Positive Edge	LED1/LED2 External Torch Mode
00	1	0	Positive Edge	X	LED1/LED2 External Flash Mode
00	1	1	0	Positive Edge	LED1/LED2 External Torch Mode
00	1	1	Positive Edge	0	LED1/LED2 External Flash Mode
00	1	1	Positive Edge	Positive Edge	LED1/LED2 External Flash Mode
10	X	X	X	X	LED1/LED2 Internal Torch Mode
11	X	X	X	X	LED1/LED2 Internal Flash Mode
01	0	X	X	X	LED1/LED2 IR Standby Mode
01	1	X	0	X	LED1/LED2 IR Standby Mode
01	1	X	Positive Edge	X	LED1/LED2 IR Mode

**Table 2. LED3 Mode Control Table**

I <sup>2</sup> C register 0x0E bits[1:0]	STROBE Enable	TORCH Enable	STROBE Pin	TORCH Pin	FUNCTION
00	X	X	X	X	LED3 Off
01	X	1	X	Positive Edge	LED3 External Torch Mode
10	X	X	X	X	LED3 Internal Torch Mode
11	0	X	X	X	LED3 IR Standby Mode
11	1	X	0	X	LED3 IR Standby Mode
11	1	X	Positive Edge	X	LED3 IR Mode

### Power Amplifier Synchronization (TX)

TX input is to reduce flash mode LED1/LED2 current during the power amplifier transmit event to limit the total battery current. When the device is working in flash mode and TX pin is pulled high, it will force the device from flash mode to torch mode with the programmed torch mode current setting. After the power amplifier transmit event and TX comes back to low, if the flash time-out event hasn't finished, the device goes back to flash mode with the programmed flash mode current setting. The device continues to work until the flash time-out event. TX event writes a '1' to the I<sup>2</sup>C register 0x0A bit[7], this fault flag will be reset to '0' once I<sup>2</sup>C register 0x0A is read back through I<sup>2</sup>C interface, or by VIN power on reset, or by I<sup>2</sup>C software reset.

### VIN Low Voltage Protection (LVP)

In LED1/LED2 flash mode, the high LED current might pull the input battery voltage low. KTD2683B has three VIN Low Voltage Protection (LVP) modes to adjust the LED1/LED2 currents based on the input voltage to prevent the battery voltage from going too low and trigger a system reset. The adjustable LVP threshold has 8 steps, ranging from 2.9V to 3.6V with 0.1V step. The three modes are "Stop & Hold", Down and "Up & Down" modes, shown in . These LVP modes only work in flash mode.

- In Stop & Hold mode, during the flash current turn on ramp, if VIN drops below the LVP threshold, after 4 $\mu$ s deglitch delay, the LED current stops rising and remains at the last value. After that, even if VIN changes, the LED current setting will not change during the remaining of the flash event.
- In Down mode, during the flash current turn on ramp, when VIN drops below the LVP threshold, after 4 $\mu$ s deglitch delay, the LED current stops rising and starts to decrease until VIN goes back to be above the LVP

threshold (or plus a hysteresis). After that, if VIN increases during the remaining flash event, the LED current setting will not change. But if VIN drops below LVP threshold again, the LED current is decreased accordingly.

- In Up & Down mode, during the flash current turn on ramp, when VIN drops below the LVP threshold, after 4μs deglitch delay, the LED current stops rising and starts to decrease until VIN goes back to be above the LVP threshold (or plus a hysteresis). Then, the LED current starts to increase until VIN drops below the LVP threshold again after the deglitch time. The flash current is repeatedly increased and decreased during the entire flash event to keep VIN close to the LVP threshold.

LVP event writes a '1' into the I<sup>2</sup>C register 0x0B bit[2], this fault flag bit resets to '0' once the register is read via I<sup>2</sup>C interface, or by VIN power on reset, or by I<sup>2</sup>C software reset.

**Figure 5. LVP Modes**

### Flash Time-out

The LED1/LED2 Flash time-out function sets the maximum time of one flash event, whether a flash stop command is received or not. The device has 16 flash time-out settings controlled by I<sup>2</sup>C register 0x08 bits[3:0], ranging from 10ms to 400ms. Flash time-out feature applies to both flash and IR modes for LED1/LED2, and it continues to count when the flash mode is switched to torch mode during TX high event. Flash time-out event writes a '1' to the I<sup>2</sup>C register 0x0A bit[0], this fault flag is reset to '0' when it is read through I<sup>2</sup>C interface, or by VIN power on reset, or by I<sup>2</sup>C software reset.

## UVLO

The device has under voltage lock-out (UVLO) function to monitor the input voltage. Once the input voltage VIN drops below UVLO falling threshold (around 2.35V), the output current is disabled and the boost converter stops switching. Once the input voltage increases above UVLO rising threshold (around 2.5V), the output current resumes its previous setting. UVLO event writes a '1' to the I<sup>2</sup>C register 0x0A bit[1], this fault flag is reset to '0' once I<sup>2</sup>C register 0x0A is read through I<sup>2</sup>C interface, or by VIN power on reset, or by I<sup>2</sup>C software reset. Even it is not read back, the device resumes normal operation once the input voltage comes back above UVLO rising threshold.

## Thermal Regulation & Thermal Shutdown

In LED1/LED2 flash or IR mode, the driver provides an automatic thermal regulation control. When the output current is high for an extended time, the IC temperature increases quickly. If the IC temperature rises above around 100°C, the output current automatically decreases according to the thermal regulation control loop. This can prevent the IC from triggering thermal shutdown and causing the LED to flicker. Depending on the PCB layout, the current setting and the turn on time, the output current may be lower than the programmed value due to the thermal regulation protection. The device also has thermal shutdown protection, when the IC temperature goes above thermal shutdown rising threshold (around 150°C), the output current is disabled and the boost converter stops switching. Once the IC temperature drops below thermal shutdown falling threshold (around 130°C), the output current resumes to its previous setting. Thermal shutdown writes a '1' to the I<sup>2</sup>C register 0x0A bit[2], this fault flag is reset to '0' once I<sup>2</sup>C register 0x0A is read back through I<sup>2</sup>C interface, or by VIN power-on-reset, or by I<sup>2</sup>C software reset. Even if the register is not read back, the device resumes normal operation once the IC temperature goes below thermal shutdown falling threshold.

## Current Limit

The boost converter has cycle-by-cycle current limit protection for its power NMOS when it is switching. Once the current limit is reached, the power NMOS turns off until the next switching cycle. The device has two current limit settings (2.8A and 1.9A) controlled by I<sup>2</sup>C register 0x07 bit[0]. Current limit event writes a '1' to the I<sup>2</sup>C register 0x0A bit[3], this fault flag is reset to '0' once I<sup>2</sup>C register 0x0A is read back through I<sup>2</sup>C interface, or by VIN power-on-reset, or by I<sup>2</sup>C software reset. The current limit function is disabled when the device is working in Pass mode because it doesn't sense power NMOS current.

## LED Short Protection

LED short protection can be enabled or disabled by I<sup>2</sup>C register 0x07 bit[3]. When LED short protection is enabled, after turn-on ramp of the output current, the device senses LED1/LED2 and LED3 pin voltages. If the LED1/LED2 pin voltage drops below around 0.5V or the voltage difference between VIN and LED3 drops below around 0.5V, after about 256µs deglitch time, the corresponding LED channel is disabled, the un-shortened channel still works. LED short condition writes a '1' to the I<sup>2</sup>C register 0x0A bit[5] or bit[4] or register 0x0B bit[5], this fault flag is reset to '0' once the corresponding I<sup>2</sup>C register 0x0A or 0x0B is read back, or by VIN power-on-reset, or by I<sup>2</sup>C software reset. Once the LED short condition is removed, the associated channel can resume normal operation by toggling the mode setting, or by disabling and then re-enabling that channel.

## LED Open Protection and Overvoltage Protection (OVP)

LED3 doesn't need LED open protection because it is outside of the boost converter control loop. For LED1 and LED2, if Boost mode is enabled while an LED is open during normal operation, the output voltage goes up to the overvoltage protection (OVP) threshold (around 5V), then the device senses LED1/LED2 voltages to automatically detect which LED channel is open and disables the open channel; then the output voltage goes back and the other normal LED channel still works. OVP event writes a '1' to the I<sup>2</sup>C register 0x0B bit[1], this fault flag is reset to '0' once I<sup>2</sup>C register 0x0B is read back, or by VIN power-on-reset, or by I<sup>2</sup>C software reset. Once the LED open condition is removed, that channel can resume normal operation by toggling the mode setting.

## Software Reset

The device has a software reset function controlled by I<sup>2</sup>C register 0x07 bit[7]. Writing a '1' to this bit resets all I<sup>2</sup>C registers to their default settings and reset all fault flags; this bit will also be reset to '0' automatically.

## Application Information

### **I<sup>2</sup>C Serial Data Bus**

KTD2683B supports the I<sup>2</sup>C bus protocol. A device that sends data onto the bus is defined as a transmitter and a device receiving data as a receiver. The device that controls the bus is called a master, whereas the devices controlled by the master are known as slaves. A master device must generate the serial clock (SCL), control bus access and generate START and STOP conditions to control the bus. KTD2683B operates as a slave on the I<sup>2</sup>C bus. Within the bus specifications a standard mode (100kHz maximum clock rate) and a fast mode (400kHz maximum clock rate) are defined. KTD2683B works in both modes. Connections to the bus are made through the open-drain I/O lines SDA and SCL.

The following bus protocol has been defined in Figure 6:

- Data transfer may be initiated only when the bus is not busy.
- During data transfer, the data line must remain stable whenever the clock line is HIGH. Changes in the data line while the clock line is high are interpreted as control signals.

Accordingly, the following bus conditions have been defined:

#### ***Bus Not Busy***

Both data and clock lines remain HIGH.

#### ***Start Data Transfer***

A change in the state of the data line, from HIGH to LOW, while the clock is HIGH, defines a START condition.

#### ***Stop Data Transfer***

A change in the state of the data line, from LOW to HIGH, while the clock line is HIGH, defines the STOP condition.

#### ***Data Valid***

The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal. The data on the line must be changed during the LOW period of the clock signal. There is one clock pulse per bit of data.

Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between START and STOP conditions are not limited, and are determined by the master device. The information is transferred byte-wise and each receiver acknowledges with a ninth bit.

#### ***Acknowledge***

Each receiving device, when addressed, is obliged to generate an acknowledge after the reception of each byte. The master device must generate an extra clock pulse that is associated with this acknowledge bit.

A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse. Setup and hold times must also be taken into account.

**Figure 6. Data Transfer on I<sup>2</sup>C Serial Bus**

KTD2683B 7-bit slave device address is 1100011 binary (or 0x63h).

There are two kinds of I<sup>2</sup>C data transfer cycles: write cycle and read cycle.

**I<sup>2</sup>C Write Cycle**

For I<sup>2</sup>C write cycle, data is transferred from a master to a slave. The first byte transmitted is the 7-bit slave address plus one bit of '0' for write. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte. Data is transferred with the most significant bit (MSB) first. Figure 7 shows the sequence of the I<sup>2</sup>C write cycle.

**Figure 7. I<sup>2</sup>C Write Cycle**

**I<sup>2</sup>C Write Cycle Steps:**

- Master generates start condition.
- Master sends 7-bit slave address (1100011 for KTD2683B) and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- Master sends 8-bit register address.
- Slave sends acknowledge.
- Master sends 8-bit data for that addressed register.
- Slave sends acknowledge.
- If master sends more data bytes, the register address will be incremented by one after each acknowledge.
- Master generate stop condition to finish the write cycle.

## I<sup>2</sup>C Read Cycle

For I<sup>2</sup>C read cycle, data is transferred from a slave to a master. But to start the read cycle, master needs to write the register address first to define which register data to read. Figure 8 shows the steps of the I<sup>2</sup>C read cycle.

**Figure 8. I<sup>2</sup>C Read Cycle**

### I<sup>2</sup>C Read Cycle Steps:

- Master generates start condition.
- Master sends 7-bit slave address (1100011 for KTD2683B) and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- Master sends 8-bit register address.
- Slave sends acknowledge.
- Master generates repeated start condition.
- Master sends 7-bit slave address (1100011 for KTD2683B) and 1-bit data direction '1' for read.
- Slave sends acknowledge if the slave address is matched.
- Slave sends the data byte of that addressed register.
- If master sends acknowledge, the register address will be incremented by one after each acknowledge and the slave will continue to send the data for the updated addressed register.
- If master sends no acknowledge, the slave will stop sending the data.
- Master generate stop condition to finish the read cycle.

## I<sup>2</sup>C Register Map

Table 3 summarizes the device I<sup>2</sup>C registers, their read/write access and default values. The I<sup>2</sup>C registers can be reset to their default values by VIN power-on-reset, or by I<sup>2</sup>C software reset.

**Table 3. I<sup>2</sup>C Register Map**

Register Name	Address (Hex)	Read/Write	Default Value
Control Setting Register	0x01	Read/Write	0x80
LVP Setting Register	0x02	Read/Write	0x01
LED1 Flash Current Register	0x03	Read/Write	0xBF
LED2 Flash Current Register	0x04	Read/Write	0x3F
LED1 Torch Current Register	0x05	Read/Write	0xBF
LED2 Torch Current Register	0x06	Read/Write	0x3F
Boost Converter Register	0x07	Read/Write	0x09
Timing Register	0x08	Read/Write	0x1A
Fault Flag 1 Register	0x0A	Read	0x00
Fault Flag 2 Register	0x0B	Read	0x00
Device ID Register	0x0C	Read	0x01
LED3 Current and Mode Register	0x0E	Read/Write	0xFC

**I<sup>2</sup>C Register Description**

The following tables summarize the setting of each I<sup>2</sup>C register. Reserved bits should be written as '0' and ignored during read.

**Table 4. Control Setting Register (Address 0x01, Read/Write)**

Bit 7 TX Pin	Bit 6 STROBE Pin Trigger	Bit 5 STROBE Pin	Bit 4 TORCH Pin	Bits [3:2] LED1/LED2 Mode Setting	Bit 1 LED2 Channel	Bit 0 LED1 Channel
0 = Disable 1 = Enable (Default)	0 = Level (Default) 1 = Edge	0 = Disable (Default) 1 = Enable	0 = Disable (Default) 1 = Enable	00 = Standby (Default) 01 = IR Mode 10 = Torch Mode 11 = Flash Mode	0 = Disable (Default) 1 = Enable	0 = Disable (Default) 1 = Enable

Note: Adjusting STROBE Level/Edge trigger setting while turning on/off flash mode using STROBE pin is not recommended. There is no timing limit for STROBE pulse width to turn on/off the flash mode.

**Table 5. LVP Setting Register (Address 0x02, Read/Write)**

Bits [7:6]	Bits [5:3] LVP Voltage Threshold	Bit 2 LVP Voltage Hysteresis	Bits [1:0] LVP Modes
Reserved	000 = 2.9V (Default) 001 = 3.0V 010 = 3.1V 011 = 3.2V 100 = 3.3V 101 = 3.4V 110 = 3.5V 111 = 3.6V	0 = 0V (Default) 1 = 50mV	00 = Disable 01 = Stop & Hold (Default) 10 = Down 11 = Up & Down

**Table 6. LED1 Flash Current Register (Address 0x03, Read/Write)**

Bit 7 LED2 Flash Current Code Override	Bits [6:0] LED1 Flash Current Code
0 = LED2 flash current code and value are set by I <sup>2</sup> C register 0x04  1 = LED2 flash current code is set by LED1 flash current code, its current value is still decided by I <sup>2</sup> C register 0x04 look-up table (Default)*	$I_{FLASH1} \text{ (mA)} = (\text{Code} + 1) \times 1500 / 128 \text{ (mA)}$ 0000000 = 11.72mA 0000001 = 23.44mA ..... 0111111 = 750mA (Default) 1000000 = 761.72mA ..... 1111111 = 1500mA

Note \*: Here are two examples below.

For  $I_{FLASH1} = I_{FLASH2} = 703.13\text{mA}$ , set register 0x03 to 0xBB (register 0x04 does not control  $I_{FLASH2}$ ).

For  $I_{FLASH1} = 703.13\text{mA}$  and  $I_{FLASH2} = 375\text{mA}$ , set register 0x03 to 0x3B and set register 0x04 to 0x1F.

**Table 7. LED2 Flash Current Register (Address 0x04, Read/Write)**

Bit 7	Bits [6:0] LED2 Flash Current Code
Reserved	$I_{FLASH2} \text{ (mA)} = (\text{Code} + 1) \times 1500 / 128 \text{ (mA)}$ , up to 750mA 0000000 = 11.72mA 0000001 = 23.44mA ..... 0111111 = 750mA (Default) 1000000 = 750mA ..... 1111111 = 750mA

**Table 8. LED1 Torch Current Register (Address 0x05, Read/Write)**

Bit 7 LED2 Torch Current Code Override	Bits [6:0] LED1 Torch Current Code
0 = LED2 torch current code and value are set by I <sup>2</sup> C register 0x06 1 = LED2 torch current code is set by the 6-bit MSB of LED1 torch current code, its current value is still decided by I <sup>2</sup> C register 0x06 look-up table (Default)*	$I_{TORCH1} \text{ (mA)} = (\text{Code} + 1) \times 187.5 / 128 \text{ (mA)}$ 0000000 = 1.465mA 0000001 = 2.93mA ..... 0111111 = 93.75mA (Default) 1000000 = 95.215mA ..... 1111111 = 187.5mA

Note \*: Here are two examples below.

For  $I_{TORCH1} = 95.215\text{mA}$  and  $I_{TORCH2} = 96.68\text{mA}$ , set register 0x05 to 0xC0 (register 0x06 does not control  $I_{TORCH2}$ ).

For  $I_{TORCH1} = 95.215\text{mA}$  and  $I_{TORCH2} = 187.5\text{mA}$ , set register 0x05 to 0x40 and set register 0x06 to 0x7E.

**Table 9. LED2 Torch Current Register (Address 0x06, Read/Write)**

Bit 7	Bits [6:1] LED2 Torch Current Code	Bit 0
Reserved	$I_{TORCH2} \text{ (mA)} = (\text{Code} + 1) \times 187.5 / 64 \text{ (mA)}$ 000000 = 2.93mA 000001 = 5.86mA ..... 011111 = 93.75mA (Default) 100000 = 96.68mA ..... 111111 = 187.5mA	Reserved

**Inductor Selection**

KTD2683B is designed to use a 0.47μH to 1.0μH inductor. To prevent core saturation, ensure that the inductor saturation current rating exceeds the peak inductor current for the application. The worst-case peak inductor current can be calculated with the following formula:

$$I_{Peak(L)} = \frac{V_{OUT(MAX)} \times I_{LED(MAX)}}{\eta \times V_{IN(MIN)}} + \frac{V_{IN(MIN)} \times t_{ON(MAX)}}{2 \times L}$$

where η is the estimated efficiency.

For example, for a 1.2A (LED1+LED2) current application, the peak inductor current for a 1.0μH inductor could be as high as (estimated 25% as the maximum duty ratio at 2MHz, efficiency of 80%, minimum input voltage of 3.5V, 4.0V of output voltage, and maximum load current conditions) :

$$I_{Peak(L)} = \frac{4.0V \times 1.2A}{0.8 \times 3.5V} + \frac{3.5V \times 0.125\mu s}{2 \times 1\mu H} = 1.93A$$

If the inductor value is smaller, the inductor peak current will increase. To maintain stable operation for the boost converter, the inductor peak current must be less than both the current limit threshold and the inductor saturation current rating. Manufacturer's specifications of inductors list both the inductor DC current rating, which is a thermal limitation, and peak inductor current rating, which is determined by the saturation characteristics. Measurements at full load and high ambient temperature should be performed to ensure that the inductor does not saturate or overheat due to its parasitic resistance. Bench measurements are recommended to confirm actual inductor peak current and to ensure that the inductor does not saturate at maximum LED current and minimum input supply voltage.

**Table 16. Recommended Inductor**

Inductor Part Number	Value (μH)	DCR (mΩ)	Saturation Current (A)	Dimensions (mm)	Manufacturer
MDMK3030T1R0MM	1.0	43	4.3	3 x 3 x 1.2	Taiyo Yuden

**Capacitor Selection**

For good voltage filtering, low ESR ceramic capacitors are recommended. A 10-μF input capacitor is recommended for high current flash LEDs to improve transient behavior of the regulator and EMI behavior of the total power supply circuit. The input capacitor should be placed as close as possible to the VIN pin and the GND pin. The output capacitance required depends on the required LED current. A 10-μF low ESR ceramic output capacitor is recommended to minimize output voltage ripple, it should also be placed as close as possible to the VOUT pin and the GND pin.

Table 17. Recommended Ceramic Capacitor Vendors

Manufacturer	Website
Murata	www.murata.com
AVX	www.avx.com
Taiyo Yuden	www.t-yuden.com

**PC Board Layout**

Due to the fast switching transitions and high-current paths, careful PC board layout is required. The input and output bypass capacitors should be placed as close to the IC as possible, these two capacitors' ground should be placed together and close to IC GND pin. Minimize the trace length between the IC and the inductor, and keep the trace short, direct, and wide.
