

3A, 2.4MHz, Low-Voltage, I²C Programmable Buck Regulator

Features

- 2.7 to 5.5V Input Voltage Range
- 0.6 to 3.345V Programmable Output Voltage
 - ▶ 6.25mV steps below 1.39375V
 - ▶ 15mV steps above 1.44V
- 3.0A Output Current
- ±1% Accuracy at T_A = +25°C
 - ▶ ±2.5% over line/load/temp/setting
- Fast Transient Response
- Dynamic Voltage Scaling (DVS) with 8 ramp rates
- Soft-Start with 10 ramp rates
- 89% Peak Efficiency at Vout = 1.15625V
- 2.4MHz with Auto-Skip at light loads
 - ▶ Programmable forced-PWM mode
- 48uA typ. No-Load Supply Current in Skip Mode
- Tiny External Components
 - ► L = 330 or 470nH (2012 or 2016 metric size)
 - Arr Cin = 10 μ F (0402), Cout = 2x22 μ F (2x0402)
- Over-Current, Short-Circuit, Under/Over-V_{IN}, and Thermal Shutdown Protections
- 1MHz I²C Interface
- Open-Drain IRQ Output Flag
- -40°C to 85°C Operating Temperature Range
- 15-bump Pb-free WLCSP (0.4mm pitch)
 - ▶ 1.340 x 2.045mm (0.6mm height)
 - ► Pin/Register Compatible with FAN53526

Brief Description

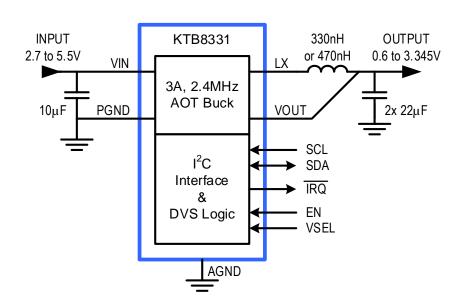

The KTB8331 is a precision adaptive-on-time (AOT) buck switching regulator with class-leading accuracy, transient response, efficiency, and solution size optimized for mobile and non-mobile application. It is I²C programmable for output voltages in the 0.6V to 3.345V range. It features soft-start and DVS with multiple programmable ramp rates. Versions with various default settings can be ordered. The features and performance make the KTB8331 suitable for a variety of applications including CPU/GPU core, DSP and baseband, DDR memory, VIO, and sensor/analog power.

The KTB8331 is available in RoHS and Green compliant 15-bump 1.340mm x 2.045mm x 0.6mm wafer-level chip-scale package (WLCSP).

Applications

- CPU, GPU, AP, DSP, FPGA, I/O, XCVR Power
- HDD, LPDDR3, LPDDR4 Memory Power
- Tablets. Netbooks. Ultra-Books
- Smartphones, Mobile Internet Devices, IoT
- DSC, Drones, Gaming Consoles, Accessories

Typical Application Schematic

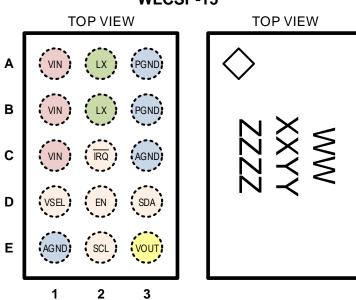

Pin Descriptions

Pin #	Name	Function
A1, B1, C1	VIN	Voltage Input for buck regulator and IC power
A3, B3	PGND	Power Ground for buck regulator
C3, E1	AGND	Analog Ground for IC power
A2, B2	LX	Inductor Connection for buck regulator
E3	VOUT	Output Voltage sense input
D2	EN	Chip Enable logic input
E2	SCL	I ² C Clock digital input
D3	SDA	I ² C Data digital I/O
C2	ĪRQ	Interrupt Request open-drain output. If not used, tie to AGND or PGND.
D1	VSEL	DVS Voltage Select and Auto-Skip vs. Forced-PWM Mode Select logic input

^{1.} Stresses above those listed in Absolute Maximum Ratings may cause permanent damage to the device. Functional operation at conditions other than the operating conditions specified is not implied. Only one Absolute Maximum rating should be applied at any one time.

^{2.} Absolute Maximum Rating for VLX is a DC voltage rating. During normal switching operation, short-duration voltage spikes beyond the DC rating are expected and normal for all DC-DC switching regulators.

^{3.} ESD Ratings conform to JEDEC industry standards. Some pins may actually have higher performance.

^{4.} Junction to Ambient thermal resistance is highly dependent on PCB layout. Values are based on thermal properties of the device when soldered to an EV board.

Functional Description

The KTB8331 is a highly efficient, high-performance, small buck regulator that operates from an input voltage of 2.7V to 5.5V and can output up to 3A. It integrates the main switch, synchronous rectifier switch, PWM control circuitry, V_{OUT} setting DAC, various protection features, and an I²C serial interface to configure the output voltage, dynamic voltage scaling (DVS), control modes, and interrupts.

Control Scheme

The KTB8331 uses a proprietary adaptive on-time (AOT) PWM control scheme to maintain a nearly constant switching frequency as input voltage and output voltage vary. Compared to typical current-mode PWM schemes, the AOT control scheme provides quick response to line and load transients with excellent stability and wide bandwidth, thereby minimizing output voltage droop and soar for dynamic loads, even with minimal output capacitance. The adaptive on-time approximates fixed-frequency switching without using a fixed clock oscillator, which eliminates the need to wait for the next clock before responding to a load transient.

The KTB8331 feedback loop also adds a proprietary, internally-compensated, integrating error amplifier to remove the output voltage offset normally associated with other AOT, constant on-time (COT), and hysteretic architectures.

Shutdown Mode

When the EN pin is low, the KTB8331 buck is in shutdown mode and draws very little current. In shutdown, the I²C is still active, allowing read and write commands, as long as V_{IN} is above V_{UVLO}. Similarly, register contents are retained during shutdown (and even when V_{IN} is a little below V_{UVLO}), as long as V_{IN} is above V_{POR}=1.8V.

Hardware Enable

The KTB8331 buck regulator is turned on and off via hardware enable using the EN pin or via software enable using I²C commands. The default register settings allow simple hardware control. For hardware enable, drive the EN pin high. For hardware disable, drive the EN pin low.

Software Enable

For software enable/disable control, first write 0 into the EN0 bit (B7) of the VSEL0 configuration register (0x00), and/or write 0 into the EN1 bit (B7) of the VSEL1 configuration register (0x01). The VSEL pin determines which register is used. Then bring the EN pin high. After that, write 1 into the corresponding EN0 or EN1 bit to enable the buck, and write 0 to disable the buck.

Soft-Start

The KTB8331 buck contains soft-start circuitry to ramp up V_{OUT} slowly in order to reduce inrush current at V_{IN} and prevent the inductor current from reaching the peak current limit (I_{LX_PEAK}) during startup. The soft-start ramp rates are I²C programmable using the SLEW[2:0] bits (B6:4) in the CONTROL configuration register (0x02).

The default register setting provides the slowest ramp rate to accommodate cold startup with certain processor cores. Once the processor is warm, faster ramps may be used. The slower rates are also better for applications with large amounts of total output capacitance. The inductor's average current during soft-start is given by:

$$I_{L SS} = C_{OUT} \times (dV/dt_{SS}) + I_{LOAD SS}$$

where dV/dtss is the soft-start ramp rate and I_{LOAD_SS} is the load current during soft-start. Choose a ramp rate that keeps the inductor current average below 3A, or even lower. As an example, if $I_{LOAD_SS} = 0$, the fastest ramp rate of dV/dtss = 30mV/ μ s is still slow enough for $I_{L_SS} \le 3A$ with $C_{OUT} \le 100\mu$ F. But if $I_{LOAD_SS} = 1.5A$ and $C_{OUT} = 300\mu$ F, choose a dV/dtss < 5mV/ μ s.

Setting the Output Voltage

The KTB8331 has two independent output voltage ranges. The low range is $V_{\text{OUT}} = 0.6\text{V}$ to 1.39375V in 6.25mV steps. The high range is $V_{\text{OUT}} = 1.44\text{V}$ to 3.345V in 15mV steps. The range is $I^2\text{C}$ programmable using the RANGE bit (B3) in the CONTROL configuration register (0x02). The default range setting is factory trimmed to match the default output voltage setting – see the *Ordering Information* section.

After the correct range is selected, the KTB8331 register map contains two voltage setting registers to facilitate hardware control of DVS using the VSEL pin. The first output voltage setting is I²C programmable using the VOUT_VSEL0[6:0] bits (B6:0) in the VSEL0 configuration register (0x00). The second output voltage setting is I²C programmable using the VOUT_VSEL1[6:0] bits (B6:0) in the VSEL1 configuration register (0x01). The output voltage setting is given by:

$$V_{OUT} = G \times (600mV + 6.25mV \times VOUT_VSELn)$$

where G = 1.0 when the RANGE bit is 0, and G = 2.4 when the RANGE bit is 1. VOUT_VSELn is the decimal equivalent of the binary bits of VOUT_VSEL0[6:0] or VOUT_VSEL1[6:0]. The default voltage settings are factory trimmed, and several versions are available – see the *Ordering Information* section.

Note: Before toggling the RANGE bit, the buck converter VOUT must be disabled either by setting EN pin to low or by setting both registers VSEL0/VSEL1 and EN0/EN1 bits to 0.

Dynamic Voltage Scaling (DVS)

Dynamic Voltage Scaling (DVS) is used to slew the output voltage between two voltage settings contained in the VSEL0 and VSEL1 registers – see *Setting the Output Voltage* section. The VSEL pin selects which register is used. Or, as an alternative method, I²C commands can be used by simply connecting the VSEL pin to ground and dynamically writing a new setting into the VSEL0 register.

In either method, all DVS output voltage transitions are slew-rate-controlled by an on-chip up/down counter and DAC. The DVS slew rate is I²C programmable using the SLEW[2:0] bits (B6:4) in the CONTROL configuration register (0x02). DVS slewing is only supported within a single output voltage range; slewing between a voltage in the low range and a voltage in the high range is *not* supported.

Forced-PWM vs. Auto-Skip Modes

The KTB8331 has two ways to control light-load switching behavior – Forced-PWM mode and Auto-Skip mode. In Forced-PWM, the switching frequency remains nearly constant. This mode is helpful for applications that are noise sensitive.

In Auto-Skip mode, the KTB8331 transitions automatically between PWM switching at heavy loads and Skip/PFM switching at light loads. Auto-Skip mode is helpful for applications that need high efficiency at light loads. While skipping, single pulses are evenly spaced, resulting in the lowest output ripple and noise when compared to competing "pulse-grouping" or "burst mode" devices. Furthermore, the PFM frequency during single-pulse skipping remains above the audio frequency band (20Hz to 20kHz) down to very light loads – see the *Typical Operating Characteristics* section.

The switching mode is I²C programmable using the MODE[1:0] bits (B1:0) in the CONTROL configuration register (0x02). The MODE[1:0] bits work together with the VSEL pin to independently set the switching mode for the VOUT_VSEL0[6:0] and VOUT_VSEL1[6:0] output voltage settings. The default mode settings are factory trimmed, and several versions are available – see the *Ordering Information* section.

Active Discharge

When the KTB8331 buck is disabled, an active discharge feature connects an on-chip resistor (R_{LX_DIS}) between the LX and PGND pins. This resistor discharges the output capacitor through the inductor. By default, this feature is enabled; however, it can be disabled for applications that require a high impedance at the output during shutdown. Enable and disable the active discharge feature via I²C commands by writing the DIS bit (B7) in the CONTROL configuration register (0x02).

POR and Software Register Reset

The KTB8331 does NOT contain non-volatile memory for the register settings. When V_{IN} rises above V_{POR} =1.8V, either at initial power up or after a temporary V_{IN} droop below V_{POR} , a Power-On Reset (POR) circuit resets all registers to their factory default settings. Thereafter, as long as V_{IN} remains above V_{POR} , the I²C registers contents are retained, regardless if the buck is enabled or disabled. However, to reliably read or write to the I²C registers, V_{IN} should be above V_{UVLO} .

August 2022 – Revision 04c Page 12 of 25 Kinetic Confidential

To reset the registers manually via software, use I²C to write a 1 to the RESET bit (B2) in the CONTROL configuration register (0x02). This resets nearly all registers to their default settings. There are a few exceptions, as makes logical sense; refer to the CONTROL register description.

Internal Status Monitor

The KTB8331 contains a MONITOR status register (0x05), which can be read to check the present status of the IC. The register has individual bits for the status of V_{OUT} power-OK, V_{IN} under-voltage lockout, V_{IN} over-voltage protection, V_{OUT} positive slew, V_{OUT} negative slew, software reset event latch, over-temperature thermal shutdown, and buck enable. Refer to the MONITOR register description for more details.

Interrupt Register and IRQ\ Flag

The KTB8331 contains an interrupt mask register, an interrupt latch register, and an interrupt request flag pin (IRQ\) to inform a host processor that one or more status changes have occurred. The INTMASK mask register (0x06) and the INTLATCH interrupt register (0x07) both partially mirror the MONITOR status register bits. However, the enable (nEN_INT) interrupt has logic inversion (in comparison to the MONITOR status register) to indicate that the buck was *disabled*.

Only unmasked events are latched into the INTLATCH register. By default, all interrupts are masked and need to be unmasked before they can be latched. The IRQ\ pin pulls active low while any bit in the INTLATCH register is a 1. Reading the INTLATCH register resets and clears the register, thereby releasing the IRQ\ pin. However, if an unmasked event is still on-going, it will not clear, and the IRQ\ pin will remain low.

This IRQ\ flag remain active during UVLO events as long as V_{IN} is above V_{POR}=1.8V. However, the IRQ\ flag is always cleared if V_{IN} falls below V_{POR} due to power-on reset (POR) of all registers.

Input Under-Voltage Lockout (UVLO)

When the input voltage (V_{IN}) is below the under-voltage lockout threshold (V_{UVLO}) , the buck is disabled. The I^2C registers and all logic pins remain functional during UVLO, so long as V_{IN} remains above $V_{POR}=1.8V$. Exiting UVLO does *not* reset any registers. When V_{IN} rises above V_{UVLO} , either at initial power up or after a temporary V_{IN} droop below V_{UVLO} , and if the buck is enabled, the programmed soft-start ramp begins.

The UVLO status is reflected in the MONITOR register. UVLO events do **not** reset the registers to their defaults. V_{IN} must fall below V_{POR} to reset the registers.

Input Over-Voltage Protection (OVP)

When the input voltage (V_{IN}) is above the over-voltage protection threshold (V_{OVP}) , the buck is disabled. The I²C registers and all logic pins remain functional during OVP. When V_{IN} returns below V_{OVP} , and if the buck is enabled, the programmed soft-start ramp begins.

Just like UVLO, the OVP status is reflected in the MONITOR register.

Inductor Over-Current Protection (OCP)

Inductor peak current limit (I_{LX_PEAK}) and valley current limit (I_{LX_VALLEY}) protect the buck and inductor during overcurrent faults. The current limits control the buck's switching on a cycle-by-cycle basis and have a higher priority than the voltage regulation threshold.

During sustained over-current faults, the output voltage typically droops below the regulation threshold. The POK_STAT bit (B7) in the MONITOR register (0x05) indicates when V_{OUT} is okay (*above* the V_{OUT_POK} threshold).

Output Short-Circuit Protection (SCP) and Hiccup Mode

During a short-circuit event at the buck's output, the inductor experiences a very low discharge voltage during the switching cycle's off-time (t_{OFF}, when the synchronous rectifier switch is on). In this case, the inductor current ramps down very slowly. In order to prevent inductor current runaway, the valley current limit (I_{LX_VALLEY}) extends t_{OFF}, keeping the inductor current well controlled.

If an over-current fault or short-circuit event persists for more than 250µs, the buck enters hiccup mode and pause all switching. After about 5ms, the buck attempts to soft-start. If the fault persists, the buck once again enters hiccup mode and periodically re-attempts soft-start until the fault is removed. The low duty-factor during hiccup mode prevents the IC from getting hot.

August 2022 – Revision 04c Page 13 of 25 Kinetic Confidential

Thermal Shutdown Over-Temperature (OT)

Over-temperature (OT) protection occurs if the die junction temperature exceeds the thermal shutdown threshold (T_{J_SHDN}). During thermal shutdown, the buck pauses all switching until the die temperature cools. Once cooled, the buck re-starts with the programmed soft-start ramp.

The OT status is reflected in the MONITOR register and, if unmasked, latched into the INTLATCH register.

Trim Options

The KTB8331 is factory trimmed using one-time programmable (OTP) registers. Standard versions are available for various default output voltage settings and modes – see the *Ordering Information* section. Contact a Kinetic Technologies representative regarding versions with other default settings or I²C slave addresses.

I²C Interface Description

I²C Serial Data Bus

The KTB8331 supports the I²C bus protocol. A device that sends data onto the bus is defined as a transmitter, and a device receiving data as a receiver. The device that controls the bus is called a master, whereas the devices controlled by the master are known as slaves. A master device must generate the serial clock (SCL), control bus access and generate START and STOP conditions to control the bus. The KTB8331 operates as a slave on the I²C bus. Within the bus specifications, a standard mode (100kHz maximum clock rate) and a fast mode (400kHz maximum clock rate) are defined. The KTB8331 works in both modes. Connections to the bus are made through the open-drain I/O lines SDA and SCL.

The following bus protocol has been defined in Figure 2:

- Data transfer may be initiated only when the bus is not busy.
- During data transfer, the data line must remain stable whenever the clock line is HIGH. Changes in the data line while the clock line is high are interpreted as control signals.

Accordingly, the following bus conditions have been defined:

Bus Not Busy

Both data and clock lines remain HIGH.

Start Data Transfer

A change in the state of the data line, from HIGH to LOW, while the clock is HIGH, defines a START condition.

Stop Data Transfer

A change in the state of the data line, from LOW to HIGH, while the clock line is HIGH, defines the STOP condition.

Data Valid

The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal. The data on the line must be changed during the LOW period of the clock signal. There is one clock pulse per bit of data.

Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between START and STOP conditions are not limited, and are determined by the master device. The information is transferred byte-wise and each receiver acknowledges with a ninth bit.

Acknowledge

Each receiving device, when addressed, is obliged to generate an acknowledge after the reception of each byte. The master device must generate an extra clock pulse that is associated with this acknowledge bit.

A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse. Setup and hold times must also be taken into account.

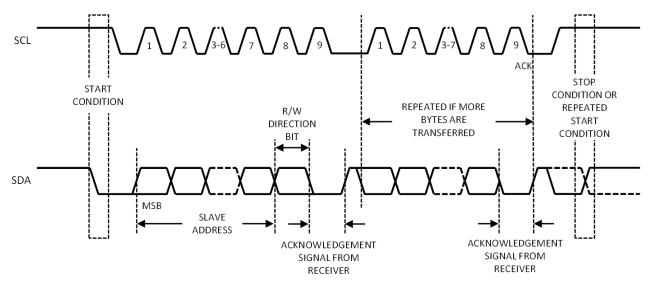

Figure 2. Data Transfer on I²C Serial Bus

The KTB8331 7-bit slave device address is listed in the Ordering Information table in page 3.

There are two kinds of I²C data transfer cycles: write cycle and read cycle.

I²C Write Cycle

For I²C write cycle, data is transferred from a master to a slave. The first byte transmitted is the 7-bit slave address plus one bit of '0' for write. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte. Data is transferred with the most significant bit (MSB) first. Figure 3 shows the sequence of the I²C write cycle.

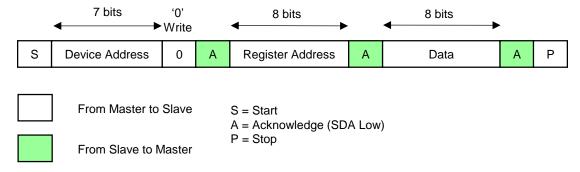

Figure 3. I²C Write Cycle

I²C Write Cycle Steps:

- Master generates start condition.
- Master sends 7-bit slave address and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- · Master sends 8-bit register address.
- Slave sends acknowledge.
- Master sends 8-bit data for that addressed register.
- Slave sends acknowledge.
- If master sends more data bytes, the register address will be incremented by one after each acknowledge.
- Master generate stop condition to finish the write cycle.

I²C Read Cycle

For I²C read cycle, data is transferred from a slave to a master. But to start the read cycle, master needs to write the register address first to define which register data to read. Figure 4 shows the steps of the I²C read cycle.

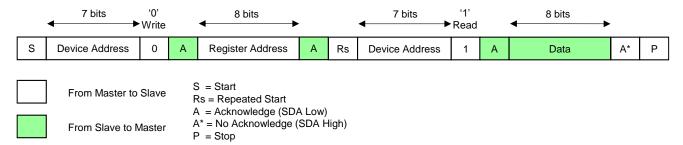

Figure 4. I²C Read Cycle

I²C Read Cycle Steps:

- Master generates start condition.
- Master sends 7-bit slave address and 1-bit data direction '0' for write.
- Slave sends acknowledge if the slave address is matched.
- Master sends 8-bit register address.
- Slave sends acknowledge.
- Master generates repeated start condition.
- Master sends 7-bit slave address and 1-bit data direction '1' for read.
- Slave sends acknowledge if the slave address is matched.
- Slave sends the data byte of that addressed register.
- If master sends acknowledge, the register address will be incremented by one after each acknowledge and the slave will continue to send the data for the updated addressed register.
- If master sends no acknowledge, the slave will stop sending the data.
- Master generate stop condition to finish the read cycle.

Register contents are reset in hardware to their default values by V_{IN} power-on reset. Additionally, most registers can be reset in software by writing 1 to the RESET bit (B2) in the CONTROL register (0x02). Default Reset bits marked with lower-case "x" in the register map and register details tables depend upon the ordered part# suffix and die revision; please see the *Ordering Information* section. Upper-case "X" used elsewhere in the tables designates "don't care".

Applications Information

Recommended Inductors

The KTB8331 is trimmed for inductors with nominal inductance of 330nH or 470nH. Select an inductor with a saturation current rating that is higher than the KTB8331 peak current limit. Also, choose an inductor with sufficient temperature-rise current rating to satisfy the RMS load-current of the application. Consider the inductor's resistance (both DCR and ACR at 2.4MHz), since these will affect the efficiency. (Generally, the ACR vs. frequency characteristic is available upon request from the inductor supplier.) Larger physical case-sizes, good winding designs, and better magnetic materials can increase efficiency. Typically, metric 2012 and 2016 case-sizes are suitable. Table 1 is a list of recommended inductors from two leading suppliers.

Table 1. Recommended Inductors

Recommended Capacitors

Ceramic input and output capacitors with X5R or X6S are recommended due to their low ESR, low ESL, low temperature coefficients, and small physical sizes. Consider the voltage rating, size, and DC bias derating characteristic of the capacitor. Table 2 is a list of recommended capacitors from two leading suppliers.

Table 2. Recommended Capacitors

Samsung E-M	CL10A476MQ8	47µF	14µF	6.3V	ASK	(0603) 1.6 x 0.8mm	

Input Capacitor

Choose an input capacitor with voltage rating of 6.3V or more, 10uF total nominal capacitance or more, and 1005M (0402) case-size or larger. Larger values and larger case-size provide more effective capacitance when considering the DC bias derating characteristic of the capacitor. If the application's input voltage is supplied through a connector or a cable, add additional bypass/bulk capacitance where V_{IN} first arrives to the PCB.

Output Capacitors

Choose output capacitors with voltage rating of 4.0V or more, 20uF total nominal capacitance or more, and 1005M (0402) case-size or larger. Consider the V_{OUT} setting of the regulator and how case size has a significant

impact on DC bias derating. At high V_{OUT} settings, more total nominal capacitance is needed to achieve the same effective capacitance compared to lower V_{OUT} settings.

For the very best possible load transient response, use multiple capacitors in parallel to achieve sufficient total effective output capacitance:

$$C_{OUT_{EFFECTIVE}} \ge \frac{L \times I_{STEP}}{33m\Omega \times (V_{IN} - V_{OUT})}$$

where I_{STEP} is the largest load transient step in the application. Please note that the above formula is already guard-banded by a margin of 2x to accommodate capacitor and inductor tolerances and the variability of a transient arrival time with respect to the switching cycle of the regulator.

If needed, the total effective output capacitance can be distributed by placing additional capacitors remotely at the point of load. In applications where transient performance is less critical, especially when V_{IN} minus V_{OUT} is small, it is acceptable to reduce the total effective output capacitance to save board space and cost at the expense of load transient droop and soar.

As a design example, consider a system with $V_{IN} = 3.2V$ (min), $V_{OUT} = 1.8V$, and $I_{STEP} = 2A$ (max):

$$C_{OUT_{EFFECTIVE}} \ge \frac{330nH \times 2A}{33m\Omega \times (3.2V - 1.8V)} \cong 14\mu F$$

In this example, choose output capacitors with total effective capacitance of $14\mu F$ or more at a DC bias of 1.8V. A single $15\mu F$ capacitor will not be enough when considering its DC bias characteristic, per Figure 5. At 1.8V bias, it retains only about $8\mu F$; therefore, for best transient response, use two of these capacitors in parallel for a total effective capacitance of $16\mu F$.

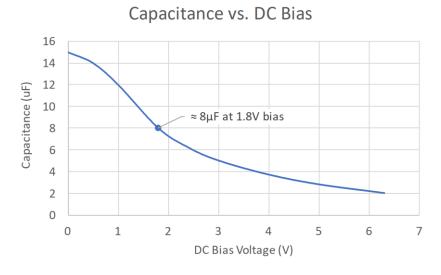

Figure 5. Typical DC bias derating characteristic for example 15µF ceramic capacitor.

When operating near dropout with high V_{OUT} and low V_{IN} (for example $3.3V_{OUT}$ and $3.6V_{IN}$), add additional bulk capacitance to C_{OUT} to reduce V_{OUT} droop and ringing during load transient events that is inherent in buck regulators operating at high duty-cycle.

August 2022 – Revision 04c Page 23 of 25 Kinetic Confidential

Recommended PCB Layout

Refer to Figure 6 for two example PCB layouts optimized for small footprint, low EMI, and good performance. One example fits in a narrow rectangular area, while the other example is nearly square. Both examples follow the below PCB layout recommendations:

- 1. Connect the input capacitor C_{IN} as close as possible to the VIN and PGND pins using top-side thick metal traces.
- 2. Connect the ground terminals of output capacitors C_{OUT} as close as possible to the ground terminal of C_{IN} and the PGND pins using top-side metal.
- 3. Connect the local top-side PGND island to the PCB ground plane using multiple parallel vias.
- 4. Do not connect the AGND pins directly to the top-side PGND. Instead, connect the AGND pins to the PCB ground plane using their own vias.
- 5. Connect the inductor to the LX pins with a wide trace. For smallest C_{IN}, the LX trace will not fit between the top-side landing pads of a 1005M (0402) size capacitor. Therefore, the LX trace is normally routed on PCB laver 2 or laver 3 using multiple parallel vias.
 - a. The added inductance of vias in series with the actual inductor have minimal effect on performance. However, it is important to use enough parallel vias to handle the peak inductor current in the application.
 - b. If using a larger C_{IN} of 1608M (0603) size or more, it is possible to squeeze the LX route on the top-side between the C_{IN} landing pads. If pinched, make sure to widen the LX trace as much as possible before and after the pinched area.
- 6. Connect the V_{OUT} terminals of the inductor to the output capacitors with a wide and short trace.
- 7. Route the V_{OUT} sense trace from C_{OUT} to the VOUT pin with care to keep it away from noisy traces, especially the LX trace. Additionally, use ground fill to shield noise from coupling into the V_{OUT} sense.
- 8. Depending upon PCB design rules, it may be possible to place filled micro-vias directly under WLCSP bumps. If not, route short traces to nearby vias.
